New research indicates that certain occupations may put workers at an elevated risk of developing rheumatoid arthritis. The findings, which appear in *Arthritis Care & Research*, suggest that work-related factors, such as noxious airborne agents, may contribute to the pathogenesis of rheumatoid arthritis.

Environmental factors are thought to play a role in the development of rheumatoid arthritis by triggering autoimmune reactions in susceptible individuals. To examine whether certain occupational hazards and exposures might be involved, Anna Ilar, of the Karolinska Institutet in Sweden, and her colleagues analyzed information from 3522 individuals with rheumatoid arthritis and 5580 controls from the Swedish population-based EIRA (Epidemiological Investigation of Rheumatoid Arthritis) study. The study gathered information on environmental, genetic, and immunological factors collected from blood samples and questionnaires between 1996 and 2014.

The team found that male workers in the manufacturing sector had a higher risk of developing rheumatoid arthritis than workers within the professional, administrative, and technical sectors (the reference group). Within the manufacturing sector, male electrical and electronics workers and material handling operators had a twofold increased risk of rheumatoid arthritis than the reference group. Bricklayers and concrete workers had a threefold increased risk.

Among women, assistant nurses and attendants had a slightly increased risk of rheumatoid arthritis. Those in the manufacturing sector did not, however. (This finding might be explained by the relatively small number of women who work in this sector compared with men.)

The researchers’ analyses took into account participants’ smoking habits, alcohol use, educational level, and body mass index, all of which are factors associated with rheumatoid arthritis. “Previous studies have not considered these lifestyle-related risk factors to the same extent. Our findings therefore indicate that work-related factors, such as airborne harmful exposures, may contribute to disease development,” said Ilar. “It is important that findings on preventable risk factors are spread to employees, employers, and decision-makers in order to prevent disease by reducing or eliminating known risk factors,” she added.

More research is needed to pinpoint the exposures that may be involved. Potential suspects include silica, asbestos, organic solvents, and motor exhaust.

**About the Journal**

*Arthritis Care & Research* is an official journal of the American College of Rheumatology (ACR), and the Association of Rheumatology Health Professionals (ARHP), a division of the College. *Arthritis Care & Research* is a peer-reviewed journal that publishes both
original research and review articles that promote excellence in the clinical practice of rheumatology. Relevant to the care of individuals with arthritis and related disorders, major topics are evidence-based practice studies, clinical problems, practice guidelines, health care economics, health care policy, educational, social, and public health issues, and future trends in rheumatology practice. The journal is published by Wiley on behalf of the ACR. For more information, please visit the journal home page at http://wileyonlinelibrary.com/journal/acr.

About Wiley
Wiley, a global company, helps people and organizations develop the skills and knowledge they need to succeed. Our online scientific, technical, medical, and scholarly journals, combined with our digital learning, assessment and certification solutions help universities, learned societies, businesses, governments and individuals increase the academic and professional impact of their work. For more than 200 years, we have delivered consistent performance to our stakeholders. The company’s website can be accessed at www.wiley.com.
